BERNOULLI SAMPLING PLANS WHICH APPROXIMATELY
MINIMIZE THE MAXIMUM EXPECTED SAMPLE SIZE
SUBJECT TO CERTAIN PROBABILITY REQUIREMENTS

# BERNOULLI SAMPLING PLANS WHICH APPROXIMATELY MINIMIZE THE MAXIMUM EXPECTED SAMPLE SIZE SUBJECT TO CERTAIN PROBABILITY REQUIREMENTS

James E. Higgins

Department of Operations Research, Cornell University

#### Abstract

Bernoulli sampling plans which approximately minimize the maximum expected sample size among all plans which guarantee certain O.C. probability requirements. Fifty-two of these plans (which would appear to be of greatest practical interest) are presented in this report. A.S.N. curve comparisons are made with plans based on the Wald sequential probability ratio test and the fixed sample size test which guarantee the same O.C. probability requirements.

#### 1. Introduction

In a paper by D. Freeman and L. Weiss [1], Weiss proposed using, for a Bernoulli population, a sequential sampling plan with an A.S.N. curve that has the smallest maximum among all sampling plans satisfying

$$P_{\theta}(\text{plan accepts the population}) \ge 1-\alpha \quad \text{if} \quad \theta \le \theta_{-1}$$
 (1.1)  $P_{\theta}(\text{plan accepts the population}) \le \beta \quad \text{if} \quad \theta \ge \theta_{1}$ 

where  $\theta$  represents the percent defective in a population and  $0<\theta_{-1}<\theta_{1}<1$ ,  $\alpha>0$ ,  $\beta>0$ ,  $\alpha+\beta<1$ . He presented the theory for constructing plans which approximately minimize the maximum expected sample size, and with Freeman developed a few examples of such plans. For all of these Weiss plans, the number of observations required by a plan is a bounded chance variable; the fact that the bound is known for each plan is of obvious practical importance. In Section 2 the theory behind the Weiss test is discussed.

Other important work in the area of sequential sampling has been done by A. Wald [9] and the Statistical Research Group at Columbia University (S.R.G.) [7,8]. Wald introduced sequential sampling plans which minimize the A.S.N. curve at  $\theta_{-1}$  and  $\theta_{1}$  among all plans satisfying (1.1), and the S.R.G. developed and cataloged sequential plans which in many instances (but not always) possess A.S.N. curves that are lower than those of single- or double-sampling plans which satisfy (1.1).

In a masters thesis [3], the author presented a catalog of 442 sequential-sampling plans as suggested by Weiss. The present paper will display 52 of these plans which are appropriate for small values of  $\theta_{-1}$ ,  $\theta_{1}$  and thus are considered to be of greatest practical interest. The A.S.N. curve characteristics of these plans will be compared with those of corresponding Wald and fixed sample size plans.

#### 2. Theoretical Development

#### 2.1 Introduction

The theory behind sampling plans which approximately minimize the maximum expected sample size was presented by Weiss [1] and will be repeated here, essentially as Weiss presented it, with remarks relating to the application of the theory in constructing plans.

#### 2.2 A Related Problem

The discussion will now center on a problem differing from but related to that described by (1.1). The exact relationship will be described later in Section 2.3. The problem to be discussed is that of constructing a sampling plan which satisfies the conditions

$$P_{\theta_{-1}}$$
 (plan accepts the population)  $\geq 1-\alpha$  
$$P_{\theta_{1}}$$
 (plan accepts the population)  $\leq \beta$  (2.1)

and which minimizes the A.S.N. curve at a specified value  $\theta_0(\theta_{-1}<\theta_0<\theta_1)$  among all plans satisfying (2.1). It is assumed that the observations taken are independent Bernoulli variables. The formulation of the above problem is aimed at controling the A.S.N. curve for values of  $\theta$  between  $\theta_{-1}$  and  $\theta_1$ .

The following notation will be employed. If T is a plan,  $P_{\theta}(A|T)$  denotes the probability that T accepts the population when  $\theta$  is the proportion of defectives.  $P_{\theta}(A|T;X_1,\cdots,X_m)$  denotes the conditional probability that T accepts the population, given that T has observed  $X_1,\cdots,X_m$  and is definitely going to observe  $X_{m+1}$  when  $\theta$  is the proportion of defectives. N denotes the number of observations that will be taken before sampling is terminated. N is a random variable whose distribution depends on  $\theta$  and on the plan used.  $E_{\theta}(N|T)$  denotes the expected value of N when T is used and  $\theta$  is the proportion

of defectives.  $E_{\theta}(N|T;X_1,\cdots,X_m)$  denotes the conditional expected value of N, given that T has observed  $X_1,\cdots,X_m$  and is definitely going to observe  $X_{m+1}$ , when  $\theta$  is the proportion of defectives. Thus  $E_{\theta}(N|T;X_1,\cdots,X_m) \ge m+1$ .

If T is a plan which minimizes  $E_{\theta_0}(N|T)$  among all plans satisfying (2.1), then there are three positive constants,  $b_{-1},b_0,b_1$ , adding to unity, such that

$$b_{-1}[1-P_{\theta_{-1}}(A|T)] + b_{0}E_{\theta_{0}}(N|T) + b_{1}P_{\theta_{1}}(A|T) \leq b_{-1}[1-P_{\theta_{-1}}(A|T')] + b_{0}E_{\theta_{0}}(N|T') + b_{1}(A|T')$$
(2.2)

for each and every plan T' (see [2], Lemma 4.1). A plan T satisfying (2.2) is called a Bayes plan with respect to the a priori distribution  $b_{-1}, b_0, b_1$ . It should be noted that the Bayes procedures are used here only as devices for constructing plans which possess certain properties. The values of  $b_{-1}, b_0, b_1$  depend on  $\alpha$  and  $\beta$ , but the exact relationship is unknown. Therefore, rather than preassigning  $\alpha$  and  $\beta$ , the values  $b_{-1}, b_0, b_1$  will be preassigned, and a Bayes plan T will be constructed with respect to  $b_{-1}, b_0, b_1$ . This Bayes plan T then has the following property. If T' is any plan satisfying the conditions

$$P_{\theta_{-1}}(A|T') \ge P_{\theta_{-1}}(A|T)$$

$$P_{\theta_{1}}(A|T') \le P_{\theta_{1}}(A|T)$$

then  $E_{\theta_0}(N|T') \ge E_{\theta_0}(N|T)$ . That is, the values 1- $\alpha$ ,  $\beta$  have been replaced in (2.1) by  $P_{\theta_1}(A|T)$ ,  $P_{\theta_1}(A|T)$ , respectively.

Define Q(m,X) as equal to unity if m=0, and as equal to

$$\frac{\theta_1^{\chi_1+\cdots+\chi_m}(1-\theta_1)^{m-\chi_1-\cdots-\chi_m}}{\theta_{-1}^{\chi_1+\cdots+\chi_m}(1-\theta_{-1})^{m-\chi_1-\cdots-\chi_m}}$$

if m>0. As characterized in Theorem 4 of [4], a Bayes plan T with respect

to a given a priori distribution  $b_{-1}, b_{0}, b_{1}$  has the following properties. There is a finite integer n and two sequences of nonnegative values,

$$a_0 \le a_1 \le \cdots \le a_n = b_{-1}/b_1, \quad r_0 \ge r_1 \ge \cdots \ge r_n = b_{-1}/b_1$$

such that T cannot observe  $X_{m+1}$ ; and for  $m=0,1,\cdots,n-1$ , T observes  $X_{m+1}$  if  $a_m < Q(m,X) < r_m$ , T does not observe  $X_{m+1}$  and rejects the population if  $Q(m,X) > r_m$ , T randomizes in any way between observing  $X_{m+1}$  or not observing  $X_{m+1}$  and rejecting the population if  $Q(m,X) = r_m$ , T does not observe  $X_{m+1}$  and accepts the population if  $Q(m,X) < a_m$ , T randomizes in any way between observing  $X_{m+1}$  or not observing  $X_{m+1}$  and accepting the population if  $Q(m,X) = a_m$ . If  $Q(n,X) = b_{-1}/b_1$ , T randomizes in any way between accepting or rejecting the population. The values  $n, a_m, r_m$  all depend on  $b_{-1}, b_0, b_1$ .

For the sake of definiteness, the only plans to be considered will be those that definitely observe  $X_{m+1}$  whenever  $Q(m,X) = a_m$  or  $r_m$  for m<n and definitely accept the population whenever  $Q(n,X) = b_{-1}/b_1$ . The characterization of T just given is presented below.

If m=0 then it is understood that  $\sum_{j=1}^{n} X_{j}$  is equal to zero. If

$$\mathbf{a}_{m} < \frac{\frac{\sum\limits_{j=1}^{m} X_{j}}{\sum\limits_{(1-\theta_{1})}^{m} \sum\limits_{j=1}^{m} X_{j}}}{\sum\limits_{\theta_{j}=1}^{m} X_{j} \sum\limits_{(1-\theta_{-1})}^{m} \sum\limits_{j=1}^{m} X_{j}} < \mathbf{r}_{m}$$

for  $m=0,1,\dots,n-1$ , then

$$\log a_{m} < \sum_{j=1}^{m} X_{j} \log \left[\frac{\theta_{1}(1-\theta_{-1})}{\theta_{-1}(1-\theta_{1})}\right] + m \log \left(\frac{1-\theta_{1}}{1-\theta_{-1}}\right) < r_{m}$$

and there is a finite integer n and values  $A_0, A_1, \dots, A_{n-1}, R_0, R_1, \dots, R_{n-1}$ , where

$$A_{m} = \frac{\log a_{m} - m \log(\frac{1-\theta_{1}}{1-\theta_{-1}})}{\log[\frac{\theta_{1}(1-\theta_{-1})}{\theta_{-1}(1-\theta_{1})}]},$$

$$R_{m} = \frac{\log r_{m} - m \log(\frac{1-\theta_{1}}{1-\theta_{-1}})}{\log[\frac{\theta_{1}(1-\theta_{-1})}{\theta_{-1}(1-\theta_{1})}]},$$

and  $A_m \leq R_m$  for all m=0,...,n-1. For n

$$A_{n} = R_{n} = \frac{\log \frac{b_{-1}}{b_{1}} - n \log(\frac{1-\theta_{1}}{1-\theta_{-1}})}{\log[\frac{\theta_{1}(1-\theta_{-1})}{\theta_{-1}(1-\theta_{1})}]}.$$
 (2.3)

Then for m=0,1,...,n-1, T observe:  $X_{m+1}$  if

$$A_{m} \leq \sum_{j=1}^{m} X_{j} \leq R_{m} ,$$

T does not observe  $\mathbf{X}_{m+1}$  and accepts the population if

$$\sum_{j=1}^{m} X_{j} < A_{m} ,$$

T does not observe  $X_{m+1}$  and rejects the population if

$$\sum_{j=1}^{m} X_{j} > R_{m} ,$$

T accepts the population if

$$\sum_{j=1}^{n} X_{j} \leq A_{n}.$$

If  $A_m$  is not an integer and m<n,  $A_m$  can be replaced by the smallest integer greater than  $A_m$ , without changing T. Similarly, if  $R_m$  is not an integer and m<n,  $R_m$  can be replaced by the largest integer less than  $R_m$ , without changing T. Henceforth, it is assumed that the changes are made, so that  $A_m$  and

R<sub>m</sub> are integers for all m<n.

For a given a priori distribution  $(b_{-1},b_{0},b_{1})$ , if  $X_{1},\cdots,X_{m}$  have been observed,  $c_{j,m}(X_{1},\cdots,X_{m})$  is defined as

$$\frac{b_{j}\theta_{j}^{X_{1}+\cdots+X_{m}}(1-\theta_{j})^{m-X_{1}-\cdots-X_{m}}}{\sum_{i=-1,0,1}b_{i}\theta_{i}^{X_{1}+\cdots+X_{m}}(1-\theta_{i})^{m-X_{1}-\cdots-X_{m}}}$$

for j=-1,0,1. The set of quantities  $(c_{-1,m}(X_1,\cdots,X_m), c_{0,m}(X_1,\cdots,X_m), c_{1,m}(X_1,\cdots,X_m))$  is called the "a posteriori distribution given  $X_1,\cdots,X_m$ ." If m=0 the quantity  $c_{j,m}(X_1,\cdots,X_m)$  is defined as equal to  $b_j$ . If T is a Bayes plan with respect to the a priori distribution  $b_{-1},b_0,b_1$  and T has observed  $X_1,\cdots,X_{m-1}$ , then T observes  $X_m$  if and only if

$$c_{-1,m-1}(X_{1}, \dots, X_{m-1})[1-P_{\theta_{-1}}(A|X_{1}, \dots, X_{m-1})]$$

$$+ c_{0,m-1}(X_{1}, \dots, X_{m-1})E_{\theta_{0}}(N|X_{1}, \dots, X_{m-1})$$

$$+ c_{1,m-1}(X_{1}, \dots, X_{m-1})P_{\theta_{1}}(A|X_{1}, \dots, X_{m-1})$$

$$\leq (m-1)c_{0,m-1}(X_{1}, \dots, X_{m-1})$$

$$+ \min\{c_{-1,m-1}(X_{1}, \dots, X_{m-1})c_{1,m-1}(X_{1}, \dots, X_{m-1})\}$$

$$(2.4)$$

for m=1,...,n. Now suppose that the values of  $A_m$  and  $R_m$  are known along with the values of  $P_{\theta_{-1}}(A|X_1,\cdots,X_m)$ ,  $P_{\theta_1}(A|X_1,\cdots,X_m)$ , and  $E_{\theta_0}(N|X_1,\cdots,X_m)$  for all  $X_1,\cdots,X_m$  with  $A_m \leq X_1 + \cdots + X_m \leq R_m$ . Then the following values can be computed:  $A_{m-1}$ ,  $R_{m-1}$ , and  $P_{\theta_{-1}}(A|X_1,\cdots,X_{m-1})$ ,  $P_{\theta_1}(A|X_1,\cdots,X_{m-1})$ , and  $E_{\theta_0}(N|X_1,\cdots,X_{m-1})$  for all  $X_1,\cdots,X_{m-1}$  with  $A_{m-1} \leq X_1 + \cdots + X_{m-1} \leq R_{m-1}$ . The method for computing the quantities mentioned above is presented in the following two paragraphs.

It is clear that  $A_{m-1} \ge A_m-1$ , for if  $A_{m-1} < A_m-1$ , then if

$$\sum_{i=1}^{m-1} X_i = A_{m-1},$$

T would observe  $X_m$  and then surely accept the population so that observing  $X_m$  would be wasteful. Similarly,  $R_{m-1} \leq R_m$ . It should be noted that for most sampling plans of a practical interest consecutive values of  $A_m$  or  $R_m$  will not be farther apart than a value of 1. If

$$\sum_{i=1}^{m-1} X_{i} = A_{m}-1 ,$$

then for all  $\theta$ , and m<n,

$$P_{\theta}(A|X_{1},\dots,X_{m-1}) = 1-\theta+\theta P_{\theta}(A|X_{1},\dots,X_{m-1},1)$$

$$E_{\theta}(N|X_{1},\dots,X_{m-1}) = (1-\theta)m+\theta E_{\theta}(N|X_{1},\dots,X_{m-1},1).$$
(2.5)

If

$$\sum_{i=1}^{m-1} X_i = R_m,$$

then for all  $\theta$ , and m<n,

$$P_{\theta}(A|X_{1},\dots,X_{m-1}) \sim (1-\theta)P_{\theta}(A|X_{1},\dots,X_{m-1},0)$$

$$E_{\theta}(N|X_{1},\dots,X_{m-1}) = \theta + (1-\theta)E_{\theta}(N|X_{1},\dots,X_{m-1},0).$$
(2.6)

If

$$A_{m}-1 < \sum_{i=1}^{m-1} X_{i} < R_{m}$$
,

then for all 0, and m<n,

$$P_{\theta}(A|X_{1}, \dots, X_{m-1})$$

$$= (1-\theta)P_{\theta}(A|X_{1}, \dots, X_{m-1}, 0) + \theta P_{\theta}(A|X_{1}, \dots, X_{m-1}, 1)$$

$$E_{\theta}(N|X_{1}, \dots, X_{m-1})$$

$$= (1-\theta)E_{\theta}(N|X_{1}, \dots, X_{m-1}, 0) + \theta E_{\theta}(N|X_{1}, \dots, X_{m-1}, 1).$$
(2.7)

Now if inequality (2.4) is satisfied when

$$\sum_{i=1}^{m-1} X_i = A_m-1,$$

(using the relations in equation (2.5) to compute the quantities in equation (2.4)) then  $A_{m-1} = A_m - 1$ . If (2.4) is not satisfied when

$$\sum_{i=1}^{m-1} X_i = A_m - 1 ,$$

then  $A_{m-1} > A_m-1$ , and  $A_{m-1}$  is the smallest integer greater than  $A_m-1$  for which (2.4) is satisfied (the quantities in (2.4) being computed by using the relations in the appropriate one of (2.6) or (2.7)). Similarly, if inequality (2.4) is satisfied when

$$\sum_{i=1}^{m-1} X_i = R_m,$$

then  $R_{m-1} = R_m$ . If (2.4) is not satisfied when

$$\sum_{i=1}^{m-1} X_i = R_m,$$

then  $R_{m-1}$  is the largest integer less than  $R_m$  for which (2.4) is satisfied (the quantities in (2.4) being computed by using the relations in the appropriate one of (2.5) or (2.7)).

If the actual value of n is known, as for example in Weiss [10], then  $A_n=R_n$  is known and is given by equation (2.3) above. The quantity  $A_n=R_n$  is not necessarily an integer and cannot legitimately be replaced by an integer if it is not already one.  $A_{n-1}$ ,  $R_{n-1}$ ,  $P_{\theta}(A|X_1,\cdots,X_{n-1})$  and  $E_{\theta}(N|X_1,\cdots,X_{n-1})$  can be computed as described previously except that on the right-hand sides of (2.5), (2.6), and (2.7)

$$\begin{split} E_{\theta}(N | X_1, \cdots, X_{n-1}, k) &= n & \text{for } k=0,1; \text{ and} \\ P_{\theta}(A | X_1, \cdots, X_{n-1}, k) &= 1 & \text{if } X_1 + \cdots + X_{n-1} + k \leq A_n, \\ P_{\theta}(A | X_1, \cdots, X_{n-1}, k) &= 0 & \text{if } X_1 + \cdots + X_{n-1} + k > A_n, \text{ for } k=0,1. \end{split}$$

Thus, if n is known, the entire plan T can be explicitly constructed, since the values of  $A_0, A_1, \cdots, A_n, R_0, R_1, \cdots, R_n$  can be found. Also, by repeated use of the recursion formulas (2.5), (2.6), and (2.7),  $P_{\theta}(A|T)$  and  $E_{\theta}(N|T)$  can be computed for any desired values of  $\theta$ . The above is accomplished when by the recursive construction the point is reached where the quantities  $P_{\theta}(A|no \text{ observations have been taken})$  and  $E_{\theta}(N|no \text{ observations have been taken})$  are sought. The proper one of (2.5), (2.6), or (2.7) is then chosen by which of the conditions the value  $\sum_{i=1}^{m-1} X_i$  satisfies (here this summation is not precisely defined but is necessarily zero since no observations have been taken).

If the actual value of n is not known before the construction of the plan starts (as is true for all cases except the symmetric ones mentioned in Weiss [10]) but it is known that  $n \le n'$ , where n' is a known finite integer, then the Bayes plan T can still be constructed as presented below. The construction technique mentioned earlier is employed, proceeding first as though n' were the correct value for n. If n' is actually greater than n, then for some value  $n \le n'$ , (2.4) will not be satisfied for any values of  $X_1, \dots, X_{n^*-1}$ , otherwise, some sample sequences would not terminate at n, which is a contradiction. This shows that  $n \le n^*-1$ , so the same construction is employed again, proceeding as though  $n^*-1$  were the correct value for n. Continuing in this way, the Bayes plan T will eventually be constructed and the value of n will be found in the process. The computation of n' will be discussed in Section 2.4.

#### 2.3 The Relation Between The Two Problems

The Bayes plan T discussed in Section 2.2 is a generalized sequential probability ratio test. Therefore, by Theorem 2 of Lehmann [5] (see also Ghosh [2]), if T satisfies (2.1), it also satisfies (1.1). This shows the

relation between the problems discussed in Sections 1 and 2.2, as far as the O.C. curve is concerned.

It is still necessary, however, to investigate the relationship between minimizing the A.S.N. curve at a given value  $\theta_0$ , and minimizing the maximum value of the A.S.N. curve for a plan which satisfies (2.1) and (1.1). Suppose T is a Bayes plan with respect to the given a priori distribution  $b_{-1}, b_0, b_1$ . Let U be any plan satisfying (1.1) with  $\alpha=1-P_{\theta_{-1}}(A|T)$ ,  $\beta=P_{\theta_1}(A|T)$ . Then U satisfies (2.1) with these values of  $\alpha$  and  $\beta$ . Define  $\Delta(T)$  as

$$\max_{\theta} E_{\theta}(N|T) - E_{\theta}(N|T),$$

so that  $\Delta(T) \ge 0$ . Then it will be shown that

$$\max_{\theta} E_{\theta}(N|U) \ge \max_{\theta} E_{\theta}(N|T) - \Delta(T).$$

That is, T comes within  $\Delta(T)$  of minimizing the maximum value of the A.S.N. curve among all plans satisfying (1.1) with  $\alpha=1-P_{\theta-1}(A|T)$ ,  $\beta=P_{\theta_1}(A|T)$ . To show the above, suppose it were not true. Then there would be a plan U satisfying the following conditions:

$$\begin{aligned} & 1 - P_{\theta-1}(A|U) \leq 1 - P_{\theta-1}(A|T) \\ & P_{\theta_1}(A|U) \leq P_{\theta_1}(A|T) \\ & E_{\theta_0}(N|U) \leq \max_{\theta} E_{\theta}(N|U) < \max_{\theta} E_{\theta}(N|T) - \Delta(T) = E_{\theta_0}(N|T). \end{aligned}$$

But the existence of a plan U satisfying these conditions would mean that T could not satisfy (2.2), which is a contradiction, since T was assumed to be a Bayes plan with respect to  $b_{-1}$ ,  $b_{0}$ ,  $b_{1}$ . This proves that

$$\max_{\theta} E_{\theta}(N|U) \ge \max_{\theta} E_{\theta}(N|T) - \Delta(T).$$

If  $\Delta(T)=0$ , then T actually minimizes the maximum of the A.S.N. curve. In Weiss [10] for a special symmetric case,  $\theta_0$  was chosen to make  $\Delta(T)=0$ .

In general, however, there is no direct means for choosing  $\theta_0$  exactly; so a value of  $\theta_0$  is chosen to make  $\Delta(T)$  reasonably small. In Section 2.2 it was pointed out that T will continue sampling longest if Q(m,X) is close to  $b_{-1}/b_1$  for all m. Define  $\overline{X}(m)$  as

$$\frac{1}{m} \sum_{i=1}^{m} X_i.$$

Then Q(m,X) can be written as

$$\begin{bmatrix} \frac{\theta_1(1-\theta_{-1})}{\theta_{-1}(1-\theta_1)} \end{bmatrix}^{m\overline{X}(m)} \begin{bmatrix} \frac{1-\theta_1}{1-\theta_{-1}} \end{bmatrix}^m.$$

If Q(m,X) is close to  $b_{-1}/b_1$ , then

$$\begin{bmatrix} \frac{\theta_1(1-\theta_{-1})}{\theta_{-1}(1-\theta_1)} \end{bmatrix}^{\overline{X}(m)} \quad \text{is close to} \quad \begin{bmatrix} \frac{1-\theta_{-1}}{1-\theta_1} \end{bmatrix} \begin{bmatrix} \frac{b_{-1}}{b_1} \end{bmatrix}^{1/m}$$

which for large m is close to  $(1-\theta_{-1})/(1-\theta_{1})$  if  $b_{-1}/b_{1}$  is not too far from unity. However, for large m,  $\overline{X}(m)$  is with high probability close to  $\theta$ , the true proportion of defectives in the population. Then it would be expected that the A.S.N. curve is high at a value of  $\theta$  such that

$$\left[\frac{\theta_1(1-\theta_{-1})}{\theta_{-1}(1-\theta_1)}\right]^{\theta} \quad \text{is close to} \quad \frac{1-\theta_{-1}}{1-\theta_1} ,$$

or at a value of  $\theta$  close to

$$\frac{\log[\frac{1-\theta-1}{1-\theta_1}]}{\log[\frac{\theta_1(1-\theta-1)}{\theta-1(1-\theta_1)}]}$$
 (2.8)

If  $b_{-1}/b_1$  is not close to unity and if there is approximate information available as to the largest number of observations the test could actually take (perhaps by interpolation among the Bayes plans presented later), then the maximizing  $\theta$  will be approximately, for large  $n^{\dagger}$ ,

$$\frac{\log[\frac{1-\theta_{-1}}{1-\theta_{1}}] + \frac{1}{n^{\dagger}} \log[\frac{b_{-1}}{b_{1}}]}{\log[\frac{\theta_{1}(1-\theta_{-1})}{\theta_{-1}(1-\theta_{1})}]},$$
(2.9)

where  $n^{\dagger}$  represents the approximate information. If the A.S.N. curve is minimized at the value of  $\theta$  given by (2.8) or (2.9), it may be expected that the maximum value of the A.S.N. curve will be approximately minimized. Therefore the value of either (2.8) or (2.9) is used in constructing the Bayes plan T, with the expectation that this choice will make  $\Delta(T)$  small.

#### 2.4 An Upper Bound on the Largest Possible Sample Size

The computation of the quantity n', an upper bound for n, will be discussed here. The quantity n' is a function of  $b_{-1}$ ,  $b_{0}$ ,  $b_{1}$ , but for typographical simplicity, the notation will not exhibit this dependence.

It would be ideal if the exact value of n were available before starting the construction of the Bayes plan T. However, at present the exact value can be found only in special symmetric cases (as in [10]); so that n' must be used, relying on the actual construction of T to find the value of n. The cruder (greater) the upper bound n', the greater the amount of computer time wasted in working back to n. Below, a value of n' is developed which is used in the construction of T. Wetherill [11] and Ray [6] have studied a different upper bound on n which has not been compared to the bound presented here.

From the discussion immediately following Lemma 4.1 and in Lemmas 4.3 to 4.6 in [4], it is found that there is a continuous nonnegative function K(u) defined for all  $u \ge 0$ , such that for  $m=0,1,2,\cdots$ ; T observes  $X_{m+1}$  if

$$c_{o,m}(X_1,\dots,X_m) < K[\frac{c_{1,m}(X_1,\dots,X_m)}{c_{1,m}(X_1,\dots,X_m)}];$$

T does not observe  $X_{m+1}$  if

$$c_{0,m}(X_1,...,X_m) > K[\frac{c_{1,m}(X_1,...,X_m)}{c_{1,m}(X_1,...,X_m)}];$$

T can randomize in any way between observing or not observing  $X_{m+1}$  if

$$c_{o,m}(X_1,...,X_m) = K\left[\frac{c_{1,m}(X_1,...,X_m)}{c_{1,m}(X_1,...,X_m)}\right];$$

and if T stops sampling immediately after observing  $\mathbf{X}_{\mathbf{m}}$ , T accepts the population if

$$\frac{c_{1,m}(X_1,\cdots,X_m)}{c_{1,m}(X_1,\cdots,X_m)}<1,$$

T rejects the population if

$$\frac{c_{1,m}(X_1,\cdots,X_m)}{c_{1,m}(X_1,\cdots,X_m)} > 1,$$

T randomizes in any way between accepting or rejecting if

$$\frac{c_{1,m}(X_1,\cdots,X_m)}{c_{1,m}(X_1,\cdots,X_m)}=1.$$

It should be noted that the function K(u) does not depend on  $b_{-1}, b_{0}, b_{1}$ . Furthermore, by the convexity of the acceptance and rejection regions described by Kiefer and Weiss in [4], K(u) has the following properties:

$$\max_{u \ge 0} K(u) = K(1) < 1$$
,  $K(0) = K(\infty) = 0$ ,

and if  $u_1, u_2$  are any two values satisfying one of the conditions  $0 \le u_1 < u_2 \le 1$  or  $1 \le u_1 < u_2$ , then for all d in the closed interval [0,1]

$$K \left[ \frac{du_{1} \left\{ \frac{1 - K(u_{1})}{1 + u_{1}} \right\} + (1 - d)u_{2} \left\{ \frac{1 - K(u_{2})}{1 + u_{2}} \right\}}{d\left\{ \frac{1 - K(u_{1})}{1 + u_{1}} \right\} + (1 - d)\left\{ \frac{1 - K(u_{2})}{1 + u_{2}} \right\}} \le dK(u_{1}) + (1 - d)K(u_{2})$$
(2.10)

In particular, setting  $u_1=0, u_2=0$  in (2.10) and denoting K(1) by k, it is found that

$$K \left[ \frac{\frac{1}{2}(1-d)(1-k)}{d+\frac{1}{2}(1-d)(1-k)} \right] \le (1-d)k$$
 (2.11)

for all d in [0,1]. Setting  $u_1=1,u_2=\infty$  in (2.10), it is found that

$$K\left[\frac{\frac{1}{2}d(1-k)+(1-d)}{\frac{1}{2}d(1-k)}\right] \le dk \tag{2.12}$$

for all d in [0,1].

If the function K(u) were known, the entire test T could be constructed explicitly, and the exact value of n would be known. However, K(u) is not known. Suppose that a known function L(u) satisfies  $L(u) \ge K(u)$  for all  $u \ge 0$ , and that n' is defined as the largest possible sample size of a plan constructed by acting as though K(u) were equal to L(u). Then it is clear that  $n \ge n$ . Furthermore, the closer L(u) is to K(u), the smaller n' will be. The next step is to construct a function L(u) which is known to satisfy  $L(u) \ge K(u)$ .

It can be said that a nonnegative value u satisfies the condition S if no Bayes plan with respect to the a priori distribution

$$\frac{1-K(u)}{1+u}$$
,  $K(u)$ ,  $u[\frac{1-K(u)}{1+u}]$ 

can ever observe  $X_2$ . From the characterization above, there is a Bayes plan  $T_O$  with respect to the a priori distribution which does not observe  $X_1$ , and there is a Bayes plan T which does observe  $X_1$ . Since  $E_{\theta_O}(N|T_O)=0$  and  $P_{\theta_1}(A|T_O)=P_{\theta_{-1}}(A|T_O)$ ,  $T_O$  makes the left-hand side of (2.2) equal to

$$\min\{\frac{1-K(u)}{1+u}, u[\frac{1-K(u)}{1+u}]\}.$$

Since  $T_1$  observes  $X_1$  but cannot observe  $X_2$ , it is clear that  $T_1$  accepts the population if  $X_1=0$  and rejects the population if  $X_1=1$ , otherwise it would not be necessary for  $T_1$  to observe  $X_1$ . Then  $E_{\theta_0}(N|T_1)=1$ ,  $P_{\theta_1}(A|T_1)=1$ , so that  $T_1$  makes the last side of (2.2) equal to

$$\theta_{-1}\left[\frac{1-K(u)}{1+u}\right] + K(u) + (1-\theta_1)u\left[\frac{1-K(u)}{1+u}\right].$$

Since both  $T_0$  and  $T_1$  minimize the left-hand side of (2.2), then

$$\theta_{-1} \left[ \frac{1 - K(u)}{1 + u} \right] + K(u) + (1 - \theta_1) u \left[ \frac{1 - K(u)}{1 + u} \right] = \min \left\{ \frac{1 - K(u)}{1 + u} , u \left[ \frac{1 - K(u)}{1 + u} \right] \right\}.$$

Using this equality, it is found that if u satisfies the condition S, then

$$K(u) = \frac{u\theta_1 - \theta_{-1}}{1 + u + u\theta_1 - \theta_{-1}} \quad \text{if } u \leq 1$$

$$K(u) = \frac{1 - u + u\theta_1 - \theta_{-1}}{2 + u\theta_1 - \theta_{-1}} \quad \text{if } u \leq 1 . \tag{2.13}$$

Next it will be shown that u=1 satisfies the condition S, so that

$$k = K(1) = \frac{\theta_1^{-\theta} - 1}{2 + \theta_1^{-\theta} - 1}$$
.

Using the a priori distribution  $\frac{1}{2}(1-k)$ , k,  $\frac{1}{2}(1-k)$ , it is found that if  $X_1=0$ ,

$$c_{0,1}(X_1) = \frac{k(1-\theta_0)}{k(1-\theta_0)+k_2(1-k)(2-\theta_1-\theta_{-1})}, \frac{c_{1,1}(X_1)}{c_{1,1}(X_1)} = \frac{1-\theta_1}{1-\theta_{-1}}.$$

Ιf

$$d = \frac{\frac{\frac{1}{2}(1-k)(\theta_1-\theta_{-1})}{1-\theta_1+\frac{1}{2}(1-k)(\theta_1-\theta_{-1})}$$

in (2.11), it is found that

$$K\left[\frac{1-\theta_{1}}{1-\theta_{-1}}\right] \leq \frac{k(1-\theta_{1})}{1-\theta_{1}+\frac{k}{2}(1-k)(2-\theta_{1}-\theta_{-1})},$$

and it is easily verified that

$$\frac{k(1-\theta_1)}{1-\theta_1+\frac{k}{2}(1-k)(\theta_1-\theta_{-1})} < \frac{k(1-\theta_0)}{k(1-\theta_0)+\frac{k}{2}(1-k)(2-\theta_1-\theta_{-1})} \ .$$

Therefore when  $X_1=0$ ,

$$c_{0,1}(X_1) > K[\frac{c_{1,1}(X_1)}{c_{1,1}(X_1)}]$$
,

so  $X_2$  cannot be observed. If  $X_1=1$ ,

$$c_{0,1}(X_1) = \frac{k\theta_0}{k\theta_0 + \frac{1}{2}(1-k)(\theta_1 + \theta_{-1})}, \frac{c_{1,1}(X_1)}{c_{-1,1}(X_1)} = \frac{\theta_1}{\theta_{-1}}.$$

If

$$d = 1 - \frac{\frac{1}{2}(1-k)(\theta_1 - \theta_{-1})}{\theta_{-1} + \frac{1}{2}(1-k)(\theta_1 - \theta_{-1})}$$

in (2.12), it is found that

$$K \left(\frac{\theta_{1}}{\theta_{-1}}\right) \leq \frac{k\theta_{-1}}{\theta_{-1}+\frac{k}{2}(1-k)(\theta_{1}-\theta_{-1})},$$

and it is easily verified that

$$\frac{k\theta_{-1}}{\theta_{-1}^{+\frac{1}{2}(1-k)}(\theta_{1}^{-\theta_{-1}^{-1}})} < \frac{k\theta_{0}}{k\theta_{0}^{+\frac{1}{2}(1-k)}(\theta_{1}^{+\theta_{-1}^{-1}})}.$$

Therefore when  $X_1=1$ ,

$$c_{0,1}(X_1) > K \left[\frac{c_{1,1}(X_1)}{c_{-1,1}(X_1)}\right],$$

so  $X_2$  cannot be observed. This proves that u=1 satisfies the condition S.

Now, a function  $L_1(u)$  is defined as follows:

$$L_1(u) = \frac{k}{1 + L_2(1-k)(\frac{1-u}{u})}$$
 if  $u \le 1$ ,

$$L_1(u) = \frac{k}{1 + \frac{1}{2}(1 - k)(u - 1)}$$
 if  $u \ge 1$ .

Using (2.11) and (2.12), it can be verified that  $L_1(u) \ge K(u)$  for all  $u \ge 0$ . Also  $L_1(u)$  is a known function of u, since k = K(1) has been computed explicitly above. Thus  $L_1(u)$  could be used as the function L(u) described above. However, more can be done by finding values of u other than unity which satisfy the condition S.

Suppose that values v,w are known, with v<l<w, such that all values u in the open interval (v,w) satisfy the condition S. Then it is known that K(u) is given by (2.13) for u in the closed interval [v,w]. Using (2.10) with  $u_1=0$ ,  $u_2=v$  yields

$$K(u) \leq \frac{K(v)}{1+(\frac{1}{u}-\frac{1}{v})(\frac{v}{1+v})[1-K(v)]} \qquad \text{for } 0 \leq u \leq v.$$

Using (2.10) with  $u_1^{=w}$ ,  $u_2^{=\infty}$  yields

$$K(u) \leq \frac{K(w)}{1+(u-w)\left[\frac{1-K(w)}{1+w}\right]} \qquad \text{for } u \geq w .$$

Therefore, L(u) can be defined as follows:

$$L(u) = \frac{K(v)}{1 + (\frac{1}{u} - \frac{1}{v})(\frac{v}{1 + v})[1 - K(v)]} \qquad \text{for } 0 \le u \le v$$

$$L(u) = \frac{u\theta_1 - \theta_{-1}}{1 + u + u\theta_1 - \theta_{-1}} \qquad \text{for } v \le u \le 1$$

$$L(u) = \frac{1 - u + u\theta_1 - \theta_{-1}}{2 + u\theta_1 - \theta_{-1}} \qquad \text{for } 1 \le u \le w$$

$$L(u) = \frac{K(w)}{1 + (u - w)[\frac{1 + K(w)}{1 + w}]} \qquad \text{for } u \ge w ,$$

and it is evident that  $L(u) \ge K(u)$  for all  $u \ge 0$ . Now the explicit values for v and w can be computed.

First it is noted that K(u) satisfies the following inequalities:

$$K(u) \ge \frac{u\theta_1 - \theta_{-1}}{1 + u + u\theta_1 - \theta_{-1}}$$

$$K(u) \ge \frac{1 - u + u\theta_1 - \theta_{-1}}{2 + u\theta_1 - \theta_{-1}}$$
if  $u \le 1$ 

$$(2.15)$$

Note that the right-hand sides of these inequalities are identical with the

right-hand sides of the equalities (2.13) which hold only for values of u satisfying the condition S, whereas (2.15) holds for all u. The proof of (2.15) proceeds similarly to that of (2.13), noting that  $T_0$  is a Bayes plan with respect to the a priori distribution

$$\frac{1-K(u)}{1-u}$$
,  $K(u)$ ,  $u \left[\frac{1-K(u)}{1+u}\right]$ .

But  $T_1$  may not hold for general u, and therefore the left-hand side of (2.2) using  $T_0$  is less than or equal to the left-hand side of (2.2) using  $T_1$ . The inequalities (2.15) then follow directly.

Define

$$v_1 = \max \left\{ \frac{\theta_{-1}(1-\theta_0)}{\theta_1+\theta_{-1}-\theta_0\theta_1-\theta_{-1}\theta_1}, \frac{\theta_{-1}+\frac{\theta_{-1}}{\theta_0}(\theta_1-\theta_{-1})}{\theta_1} \right\}.$$

Then  $o < v_1 < 1$ , and a straightforward but somewhat tedious calculation shows that if u is the open interval  $(v_1, 1)$  and if a Bayes plan is constructed with respect to the a priori distribution

$$\frac{1-K(u)}{1+u}$$
,  $K(u)$ ,  $u \left[\frac{1-K(u)}{1+u}\right]$ ,

then

$$c_{0,1}(X_1) > L_1 \left[\frac{c_{1,1}(X_1)}{c_{-1,1}(X_1)}\right]$$

For  $X_1=0$  or 1, (the first inequality in (2.15) is used in the calculation). Since  $L_1(u) \ge K(u)$  for all u, then any u in  $(v_1,1)$  satisfies the condition S.

$$w_{1} = m_{1} \cdot \left\{ \frac{(1-\theta_{0})(1-\theta_{-1})}{(1-\theta_{1})(1+\theta_{1}-\theta_{0}-\theta_{-1})} , \frac{1-\theta_{-1}-(\frac{\theta_{-1}}{\theta_{0}})(\theta_{1}-\theta_{-1})}{1-\theta_{1}} \right\}.$$

Then  $w_1>1$ , and calculation shows that if u is in the open interval  $(1,w_1)$ 

and if a Bayes plan is constructed with respect to the a priori distribution

$$\frac{1-K(u)}{1+u}$$
,  $K(u)$ ,  $u\left[\frac{1-K(u)}{1+u}\right]$ ,

then

$$c_{0,1}(X_1) > L_1 \left[ \frac{c_{1,1}(X_1)}{c_{-1,1}(X_1)} \right].$$

For  $X_1=0$  or 1, the second inequality in (2.15) is used in the calculation. Since  $L_1(u) \geq K(u)$  for all u, then any u in  $(1,w_1)$  satisfies the condition S. Now define  $L_2(u)$  as L(u) was defined in (2.14), using  $v_1,w_1$  in place of v,w. Clearly,  $L_2(u) \geq K(u)$  for all u. Noting that  $v_1,w_1$  is found by using the fact that  $L_1(u) \geq K(u)$  for all u, and noting that  $L_1(u) \geq L_2(u) \geq K(u)$  for all u, it would be possible to find values  $v_2,w_2$ , such that all u in  $(v_2,w_2)$  satisfy the condition S, where  $v_2 < v_1,w_2 > w_1$ . The quantities  $v_2,w_2$  would be computed using  $L_2(u)$  just as  $L_1(u)$  was used in computing  $v_1,w_1$ . Then, using  $v_2,w_2$  in (2.14), there would be a function  $L_2(u)$  with  $L_2(u) \geq L_2(u) \geq K(u)$ . The above process could be continued. Since the establishment of an upper bound n' may be of only relative importance in the wholesale construction of the Bayes plans, the known function  $L_1(u)$  defined by using v,w in (2.14) was used here as the final function L(u).

For a given a priori distribution  $b_{-1}, b_0, b_1$  define z(m) as the largest integer for which  $Q(m, X) \leq b_{-1}/b_1$  when  $X_1 + \cdots + X_m = z(m)$  for each positive integer m. Then from Section 2.2, it is known that if a Bayes plan cannot observe  $X_{m+1}$  when

$$\sum_{i=1}^{m} X_{i} = z(m)$$

or z(m)+1, the plan cannot observe  $X_{m+1}$  under any circumstances. Define c(m)

as the value of  $c_{0,m}(X_1,\dots,X_m)$  when

$$\sum_{i=1}^{m} X_{i} = z(m) ,$$

and define c'(m) as the value of  $c_{0,m}(X_1, \dots, X_m)$  when

$$\sum_{i=1}^{m} X_{i} = z(m)+1.$$

Define f(m) as the value of

$$\frac{c_{1,m}(X_1,\dots,X_m)}{c_{-1,m}(X_1,\dots,X_m)} \quad \text{when} \quad \sum_{i=1}^m X_i = z(m) ,$$

and f'(m) as the value of

$$\frac{c_{1,m}(X_1,\dots,X_m)}{c_{-1,m}(X_1,\dots,X_m)} \quad \text{when} \quad \sum_{i=1}^m X_i = z(m)+1.$$

Define n' as the smallest integer satisfying both of the following inequalities:

$$c(n') > L_1(f(n'))$$
  
 $c'(n') > L_1(f'(n'))$ .

If  $L_1(u)$  were equal to K(u), the Bayes plan could not observe  $X_{n'+1}$ . Since it is known that  $L_1(u) \ge K(u)$  for all u, it is also known that the Bayes plan can never observe  $X_{n'+1}$ . Therefore n' is the upper bound for n described in Section 2.2.

Since n' is a discrete variable and  $b_0$  is a continuous variable, in the actual computation it is easier to reverse the above process and search for  $b_0$ , rather than for n'. The reverse process is completed by fixing a positive integer m and a value for the ratio  $b_{-1}/b_1$ ; then z(m), f(m), and f'(m) can be computed without knowing the value of  $b_0$ . Define  $b_0'(m, b_{-1}/b_1)$  as the smallest value of  $b_0$  that makes both of the following inequalities hold:

$$c(m) \ge L_1(f(m))$$
  
 $c'(m) \ge L_1(f'(m))$ .

Then it is clear that there is a Bayes plan with respect to the a priori distribution  $b_{-1}, b_0'(m, b_{-1}/b_1), b_1$  which never observes  $X_{m+1}$ , where in this a priori distribution  $b_{-1}/b_1$  is equal to the fixed given ratio. Then the entire Bayes plan can be constructed by working back from m as the upper bound on the number of observations.

# 3. Sequential Sampling Plans Which Approximately Minimize the Maximum Expected Sample Size

The format of each plan (the order of plans is listed in the table of contents by values of  $\theta_{-1}, \theta_{1}, \alpha, \beta$ ) is similar to the following example:

$$\theta_{-1} = .001$$
  $\theta_{1} = .011$   $\alpha = \beta = .01$ 

Plan 1

#### Comparison of A.S.N. Values

Test	$\theta = .001$	Maximizing $\theta$	$\theta = .011$
Minimax	611.5	735.0	321.0
Wald	568.9	885.0	285.8
Fixed Sample Size		965.0	

n	A <sub>n</sub>	Rn	n	An	R <sub>n</sub>
1 3 242 519 664 677 838	  0 0 1 2 3	3 4 4 5 5 5 6 6	1346	5	6
1001 1046 1171	3 4	6			

The Minimax test refers to the one introduced by Weiss [1]. A.S.N. values for the Wald test [9] were computed using the Wald approximation formulas, and the number of observations required by the fixed sample size test was computed using a normal approximation. The  $\alpha,\beta$  values are approximately those for the given plan. The exact  $\alpha,\beta$  values can be found in [3]. A.S.N. values for the Minimax and Wald tests are compared at  $\theta_{-1},\theta_{1}$  and the "Maximizing  $\theta$ ." The value of  $\theta$  associated with the maximum A.S.N. is usually different for the two sequential tests.

The acceptance and rejection numbers at stage n, are labeled  $A_n$ ,  $R_n$  respectively. The batch of product being sampled is accepted if the cumulative

number of defectives after the  $n\frac{th}{}$  observation is no greater than  $A_n$  and is rejected if the cumulative number of defectives is no less than  $R_n$ . Otherwise, another observation is taken, and the comparison is repeated. If the  $A_n$  column is dashed for the  $n\frac{th}{}$  observation, the batch cannot yet be accepted, and if the  $R_n$  column is dashed for the  $n\frac{th}{}$  observation, the batch cannot yet be rejected. The values of  $A_n$  and  $R_n$  are only listed when one or both change value. For example, in Plan 1 presented above no decision to accept or reject can be made until three observations have been taken, for the  $3\frac{rd}{}$  through the  $241\frac{st}{}$  observations the batch cannot be accepted but can be rejected if a total of 3 or more defectives is observed, etc. The last entries in the  $A_n$  and  $R_n$  columns differ by one unit and force sampling to terminate if it reaches this point.

$$\theta_{-1} = .001$$
  $\theta_{1} = .001$   $\alpha = \beta = .01$ 

$$\theta_1 = .001$$

$$\alpha = \beta = .01$$

13 ABSTRACT

The author, in his masters thesis, constructed a catalog of 442

Bernoulli sampling plans which approximately minimize the maximum expected sample size among all plans which guarantee certain O.C. probability requirements. Fifty-two of these plans (which would appear to be of greatest practical interest) are presented in this report. A.S.N. curve comparisons are made with plans based on the Wald sequential probability ratio test and the fixed sample size test which guarantee the same O.C. probability requirements.

#### INSTRUCTIONS

- 1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.
- 2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.
- 2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.
- 3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.
- 4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.
- 5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.
- 6. REPORT DATE: Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.
- 7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.
- 8.a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 8b, &c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, tack number, etc.
- 9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.
- 9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).
- 10. AVAILABILITY LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

- 11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.
- 12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.
- 13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional
